R Markdown

1. `install.packages()` downloads and saves a package onto your computer, while `library()` loads that installed package into your current session so you can use its functions. You only need to install a package once because the files stay stored on your hard drive, but you have to load it every session because R resets its active workspace whenever you open a new session.
2. The `<-` operator assigns a value or data object to a variable name. Most R programmers prefer `<-` over `=` because `<-` clearly points to the direction of assignment and avoids confusion, as `=` is also used for assigning argument values inside function calls.
3. The Source pane is used to write and save your scripts, while the Console pane executes commands directly and is where you can install packages using code. The Environment/History pane lets you check the content of created objects and dataset values. The Files/Plots/Packages/Help pane shows your outputted graphs, files, and installed packages, so you would use it to view a plot.
